Background & Aim

Antibody-induced glomerulonephritis (GN) is a condition caused by an inappropriate autoimmune response to renal antigens, such as the glomerular basement membrane (GBM), leading to progressive glomerulosclerosis and rapidly declining renal function for which there exist only few treatment options. Understanding the underlying mechanisms of GN is crucial for developing effective therapeutic strategies. In this study, we aimed to investigate the induction of antibody-induced GN by anti-GBM serum on kidney biomarkers, histology and transcriptome signatures.

Methods

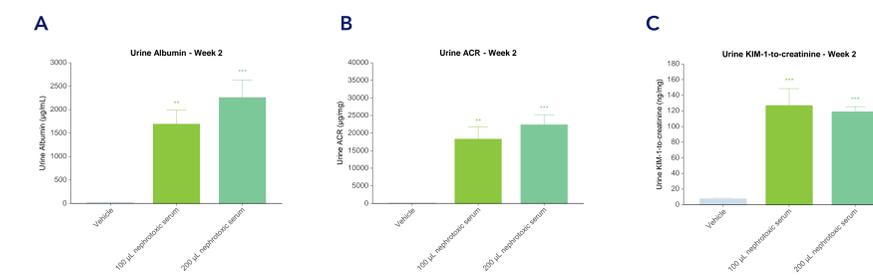

Male C57BL/6J mice (n=12) were randomized into three groups (n=4 per group) and received either vehicle injection, 100 or 200 µl of anti-GBM serum. We measured urine albumin-to-creatinine ratio (ACR) as an indicator of renal damage. Renal endpoints included urine albumin-to-creatinine ratio (ACR), AI-assisted glomerulosclerosis scoring, histomorphometric analysis of fibrosis (Col3a1), and RNA sequencing (RNA-seq) analysis.

1 Study outline

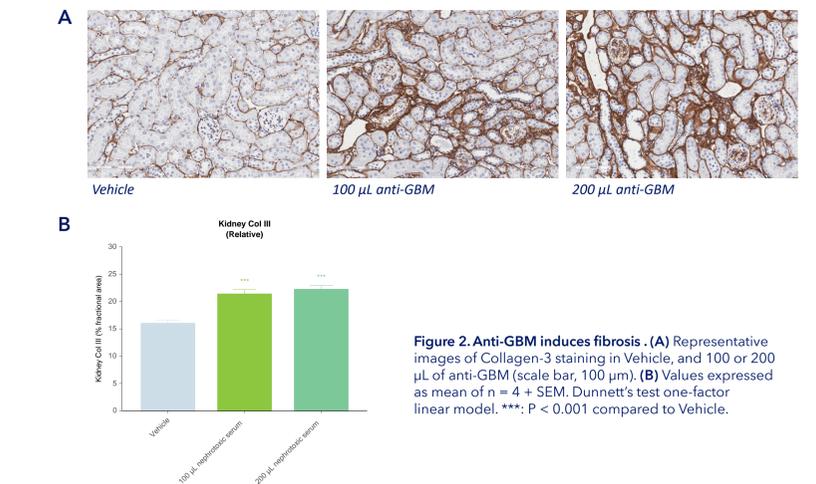

Group	Animal	Gender	Number of animals	Treatment	Dosing Volume (µl)	Dosing concentration
1	Control	male	4	Vehicle	150	xx
2	Anti-GBM nephritis	male	4	NTS	100	xx
3	Anti-GBM nephritis	male	4	NTS	200	xx

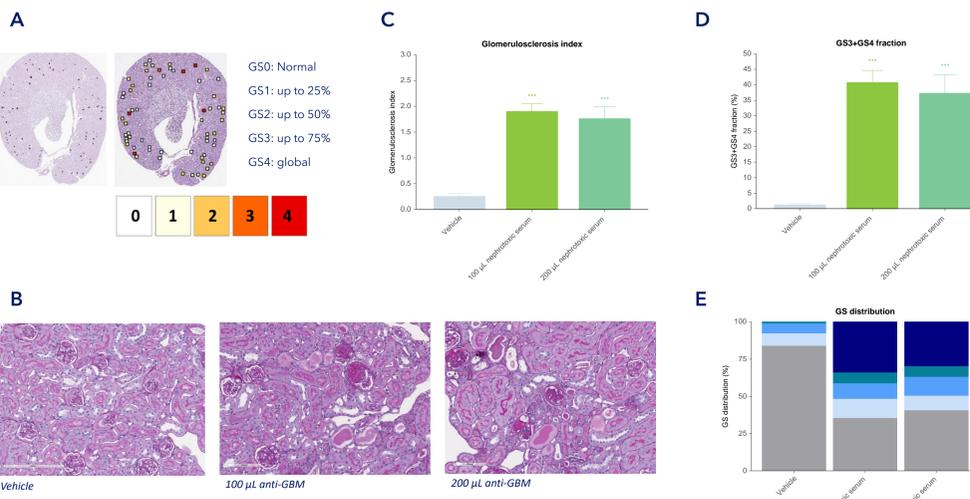

2 Anti-GBM serum increases urine Albumin, ACR and KIM-1 to Creatinine

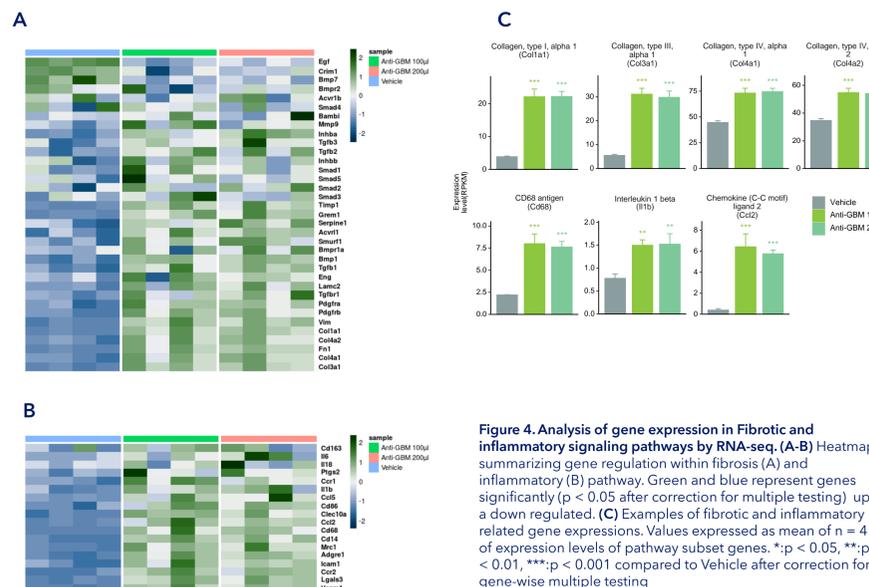

3 Anti-GBM serum develops kidney fibrosis

5 AI-assisted Glomerulosclerosis scoring increases after anti-GBM induction

4 Inflammatory and fibrotic signalling intensifies following the anti-GBM dosage

Conclusion

- + Anti-GBM serum induces fast onset of renal damage, glomerulosclerosis, and fibrosis in the mouse model of antibody-induced GN.
- + Anti-GBM also induces the up-regulation of genes involved in inflammatory and fibrosis.
- + The antibody-induced GN model in mice is highly applicable for probing test compounds with potential nephroprotective effects autoimmune GN.
